

Connect to your Navon Cloud server

SSH quick-start for researchers and teams

You can register your own SSH key and connect to a server from your laptop in a few minutes. You do this yourself in the portal, no need to send your key to anyone.

The idea in one line: an SSH key has two halves, a **private key** that stays secret on your laptop, and a **public key** that is safe to share. You add the public key to your account, and you connect with the private key. Never share the private key.

Step 1 — Make your key

On a Mac open **Terminal**, paste this, and press **Enter** a few times:

```
ssh-keygen -t ed25519
```

On Windows open **PowerShell**, paste this, and press **Enter** a few times:

```
ssh-keygen -t ed25519
```

(If Windows says "command not found": Settings, Apps, Optional Features, Add "OpenSSH Client", then try again.)

Step 2 — Copy your PUBLIC key

Mac (copies it to your clipboard):

```
pbcopy < ~/.ssh/id_ed25519.pub
```

Windows:

```
Get-Content $env:USERPROFILE\.ssh\id_ed25519.pub | clip
```

Your public key is one line that starts with `ssh-ed25519 AAAA...`.

Step 3 — Add the key yourself in the portal

1. Sign in to the portal at portal.navon.africa.
2. Go to **Settings**, find the **SSH keys** section, and click **Add key**.
3. Give it a **Name** (for example "My laptop"), paste your **public key** into the **Public key** box, and click **Add key**. You can add more keys here any time.

Step 4 — Turn it on for a server

Assign the key to the server you want to use, either from the **SSH keys** section in Settings or from the server's own **SSH access** option. A single server can hold several keys, so a whole team can share one server.

If you do not see a server yet, ask your administrator to share the grid with your account.

Step 5 — Connect

Open **Terminal** (Mac) or **PowerShell** (Windows) and use the address, username and port shown for the server:

```
ssh USERNAME@SERVER-ADDRESS -p PORT
```

You are now on the Navon Cloud server, with the GPU ready to use.

Prefer VS Code? Install the **Remote - SSH** extension, choose **Connect to Host**, and enter the same `USERNAME@SERVER-ADDRESS` (and port). You will be editing and running right on the server.

Quick tips

- Keep your **private key** private. Never share the file without `.pub`, and never paste it into any website.
- One key is enough. It works for every server you are given access to.
- New laptop or lost key? Just redo Step 1 and add the new public key.
